Not illustrated. 1887 Excerpt: ... upon the strain, of B, but wholly independent of the velocity of A or B. We have supposed the bullet and string to be moving with the same velocity, in order to make sure that the strain of the spring was always the same. If however the same condition of strain could be secured in any other way, the acceleration would be found quite independent of the velocity of the spring. MASS. If we now cut the bullet in two, and use one half in the same way, we shall find that for any given state of strain of the spring the acceleration is double what it was before. And generally, if we use any other piece of lead we shall find that the accelerations in the two cases are inversely proportional to the volumes of the pieces of lead; or, we may say, to the quantities of lead. The same thing is true if we take different pieces of wood, or of any other substance, provided that the substance is homogeneous, that is, of the same nature all through. But if we compare the accelerations of a piece of wood and a piece of lead, we shall find that they are by no means inversely proportional to the volumes of the two bodies. A piece of wood, whose acceleration in the same circumstances is the same as that of a piece of lead, will be very much larger than the lead. Let us now take an arbitrary body, say a certain piece of platinum. Of every other sort of substance, as of lead, wood, iron, etc., let us find a piece which under the same circumstances (i.e. with the same strain of the spring) has the same acceleration as the piece of platinum, and let each of these be called the unit of quantity of the substance of which it is composed. Then if we consider a homogeneous body composed of one of these substances, the number of units of quantity which it contains is called the mass or mea...
